#### Introduction

- Previous works:
- → Considers only long-tailed anomaly detection or only noisy/contaminated anomaly detection
- Noisy long-tailed anomaly detection:
- → Realistic scenario which is more challenging. Solving such task is practical.
- Setup
- → Only head class is contaminated with noisy samples and tail class (< 20samples) exists.

**Motivation** 

1) Noise discriminative models, such as SoftPatch removes statistically minor patches assuming less frequent data is noise. However, this accidently also removes tail classes as shown in the figure above (red bar).

2) Greedy sampling used in patchcore samples tail classes well due to the nature of greedy sampling, however, also favors noisy patches as well as shown in the figure above (green bar)

## Contributions

- · Suggest a practical and challenging anomaly detection scenario: noisy long-tailed anomaly detection
- Propose a memory-based anomaly detector TailedCore whose memory bank is both noise-free and augmented with tail class features utilized by an exclusive tail-class sampler TailSampler which estimates class size.
- Analyze proposed TailedCore and compare with few-shot and noise discriminative anomaly detection methods.

## Method

## **Pipeline:**

- TailSampler : Selectively sample long-tail class samples while excluding noisy samples with GAP features as global features are less affected by anomalies(noise) which are mostly local attributes.
- Denoise with existing noise discriminative methods (e.g. **SoftPatch**) with  $S_{clean}(P)$
- Collect patch features  $S_{tail}(P)$  from **TailSampler** and merge with denoised patches

## TailSampler:

le p, estimate the neighbors of embedding 
$$e_i$$
,  
 $H_i = \{e \in \mathbb{Z}: \forall (e_i, e_i) \leq e_i\}$ 

for every  $e_i$  with the set of all embeddings Z, where

$$m_i \coloneqq \max \measuredangle(e_i)$$

• With  $\alpha_i$  and

$$N_{\alpha}(e_i) = \{e \in Z : \measuredangle(e_i)\}$$

denoting the neighborhood of  $e_i$  (the set of all train embedding e within angle  $\alpha$  of  $e_i$ ) estimate its class size based on neighborhoods of neighborhoods by

$$\kappa_i = \operatorname{mode}_{e \in N\alpha_i(e_i)}(|N_{\alpha(e)}|)$$

where  $\alpha(e)$  is the adaptive angle with respect to embedding *e* belonging to the neighborhood  $N_{\alpha_i}(e_i)$  of embedding  $e_i$ . • With  $\kappa_i$ , estimate size of each classes  $\eta_{\nu} \approx |C_{\nu}|$  inductively by

$$y) = round \left(\frac{1}{\kappa_{\eta(y)}} \sum_{i=\eta_y}^{\min(\kappa_{\eta})} \right)$$

and find maximum size of tail classes with elbow technique where  $\eta_i$  abruptly changes.

## **Experiments & Results**

- Dataset setup : Pareto / Step K=4 / Step K = 1 (K is number of long-tail class samples). For step, 60% of the classes are long-tailed. Head classes are all contaminated (10% for MVTec, 5% for VisA)
- **TailedCore** outperforms few shot methods (**WinCLIP**, **AnomalyCLIP**) with noisy samples  $(C_h)$  and exceeds noise discriminative models (**SoftPatch**) on tail classes  $C_t$

## Ablation (Tail Class Sampler)

- Classification accuracy of tail-classes/noisy samples (x-axis) vs metrics (y-axis) relevant to class size prediction and few-shot sampling with step K=4. (a to h from left to right and top to bottom)
- Correlation is strong for (a) mis-sampling ratio, (b) ratio of missing few-shot samples, (e) class size prediction error, and (f) AUROC for few-shot prediction.
- Better embeddings improve TailSampler which in turn improves (g) anomaly classification (image-level AUROC) and (h) anomaly segmentation (pixel-level AUROC) performance.

## Ablation (noise ratio)

## Limitation

**TailSampler** can fail if

- The reflective-symmetric assumption on inter, intra-class similarities break down (by poor embedding representation or not aligned with label space well)
- Geometric aspects of defect samples are similar to few-shot class instances in the embedding space.

## Conclusion

- We introduce a novel unsupervised anomaly detection task, noisy long-tailed anomaly detection.
- We suggest TailedCore utilized with TailSampler, a unique class size predictor, and successfully navigated the tailversus-noise dilemma by exclusively sampling the tail classes, enhancing performance of noisy long-tailed anomaly detection.
